

MP2

In this Mini-Project, following certain specifications, you will create a React-App where information is retrieved from an **API**, and is displayed by **Component**.

Task-1:

- Please check out this repository on GitHub, and study its code:
<https://github.com/tazmanianDeveloper/mp-2>
 1. Notice how the **App** Component is using Hooks for API handling and that it is passing the retrieved data to another component.
 2. Notice how the **RickAndMorty** Component is receiving the data as props and generates content for the UI.
 3. In your assignment you must adhere to this **single-tasking** principal as well. This means that you would have to have **at least 2 components for MP-2**, where one retrieves data and the other uses the data to build the UI.
- Using **Vite**, recreate the project on GitHub but with a different **API**.
- Using the Terminal/CMD, start your **mp-2**:

cd into your working **directory**: ~ % cd WebstormProjects

create and empty Vite project: WebstormProjects % npm create vite@latest

Using *spinal-case* name you project (e.g., mp-2): ? Project name: > mp-2

Using *arrow-keys* select **React**: ? Select a framework:
Vanilla
Vue
> React
Preact
Lit
Svelte
Solid
Qwik
Others

Using *arrow-keys* select **TypeScript + SWC**: ? Select a variant: >
TypeScript
> TypeScript + SWC
JavaScript
JavaScript + SWC
Remix ↗

SWC is a Node.js Compiler

Done
Scaffolding project
Done. Now run:
cd mp-2
npm install
npm run dev

You can do this part from your IDE

- You can find free APIs from these sites:
<https://free-apis.github.io/#/>
<https://mixedanalytics.com/blog/list-actually-free-open-no-auth-needed-apis/>
<https://apipheny.io/free-api/>

Note:

The API must be served from a **secure server** (<https://>).

The API must **not require an API key**.

The API must **not have CORS restrictions**.

Ex:

- If you decided to use a different API (not from the links above), please run it by me first, before you start the development.
- Change fields of your components based on the content of the API you chose. For example, for each character in the “Rick and Morty” API, that character’s, id, name and image are used. Should you decide to use the “Rick and Morty” API, you must add 3 additional fields, (not covered in the GitHub sample). Ultimately regardless of what API you chose, **you have to have at least 3 fields** for each object.
- In terms of styling, you may resort to the traditional approach globally, but your child components must be designed using “**styled-components**”. Limit your traditional styling only to the global component or to index.html.

Task-2:

Deployment:

1. In your terminal, navigate to the root of the directory of your project (mp-2) and use the command **git init**
2. Use the command **git status** to see the current status of the files within your directory. Right now, all files should be untracked
3. Use the command **git add filename** or **git add .** (to add all files). This tells Git about any changes you’ve made to this file since its last commit.
4. Once you have added all relevant files, use the command **git commit -m “your commit message”** to commit your changes. This confirms your staged changes with Git. Be sure to include a helpful/informative commit message when using this command.

5. Create a new GitHub repository by visiting <https://github.com> and clicking **New** on the left next to **Top Repositories**
6. Give your repository the same name as the directory you're working in (**mp-2**) and click **Create repository**
7. Follow the directions under **or push an existing repository from the command line** in your terminal
8. You may be prompted by Git to use the command **git push --set-upstream origin main**. If you are, do so.
9. Your files should now be on GitHub! Refresh your GitHub tab if you don't see your files.
10. Once you saw your files, **Save the URL**:
(e.g., https://github.com/YOUR_USER_NAME/mp-2).

Hosting:

1. Visit <https://vercel.com/signup> and set up a free (Hobby) account (you might have done this already in **Dis-1**).
2. Connect your GitHub account to your Vercel account.

3. Once connected all of your GitHub repositories will be listed in Vercel. Select **mp-2** from the list and push the **import** button next to it.
4. In the next screen you don't need to change anything; just click **Deploy**. Vercel will take a few seconds to process the files and will prompt you with a "Congratulations" message and a screenshot of your hosted app.
5. Click on the screenshot, which should open a new browser-tab, **save its URL**:
(e.g., <https://mp-2.vercel.app>).

Submission:

- Create simple **text file** with any writing platform (MS-word, notepad, etc.)
- Write your first-name, last-name, and BU-username on top.
- Paste **both saved URLs** in the text filed:

(e.g., https://github.com/YOUR_USER_NAME/mp-2).

(e.g., <https://mp-2.vercel.app>).

- You Link might be different from the ones above, so make sure that both open to your assignment before you submit them.
- Add comments if you like, and click **submit**.
- Convert it to **PDF** as **mp-2.pdf**.
- Navigate to [gradescope](#), find CS-391, find this assignment, and submit it as: (**mp-2.pdf**).

Note:

DON'T UPDATE/PUSH/change your assignment's GitHub repo after the **due-date**. **Altering your assignment after its due-date is considered cheating** and at minimum, will result in an automatic 0 on that assignment.

You may change or alter that repository after you received a grade on that assignment.
